## Athlete's Data

23-year-old woman participating in a research project looking at iron metabolism in three groups; pill, regular menses and menopause. After a medical examination and a maximal test, she performed intermittent exercise on the treadmill. The maximal parameters as well as the characteristics of the intermittent exercise are shown in (Table 1).

| Height | 155 cm |
| :---: | :---: |
| Weight | 55 Kg |
| Body surface Area | 1,53 m ${ }^{2}$ |
| $\mathrm{FEV}_{1,0}$ | 2,76 L |
| FVC | 3,18 L |
| $\dot{\mathrm{V}}_{2}$ max | $2772 \mathrm{ml} / \mathrm{min} ; 49,6 \mathrm{ml} / \mathrm{Kg} / \mathrm{min}$ |
| $\dot{\mathrm{V}}_{\mathrm{Emax}} ; \mathrm{VT}_{\text {max }} ; \mathrm{BR}_{\text {max }}$ | $115 \mathrm{~L} ; 1,7 \mathrm{~L} ; 65 \mathrm{resp} / \mathrm{min}$ |
| Max HR; Max Pulse $\mathrm{O}_{2}$ | $180 \mathrm{lat} / \mathrm{min} ; 15,4 \mathrm{ml} /$ heartbeat |
| $\mathrm{RQ}_{\text {max }}$ | 1,16 |
| maximum running speed on the treadmill | 16,9 Km/h |
| Ventilatory threshold $1\left(\mathrm{VT}_{1}\right)$ | $82 \%$ del $\dot{\mathrm{VO}}_{2}$ max $75 \mathrm{~L} / \mathrm{min}$ 161 latidos/min $13,2 \mathrm{Km} / \mathrm{h}$ |

|  | $97,1 \%$ del $\dot{\mathrm{V}} \mathrm{O}_{2} \max$ |
| :--- | :--- |
| Ventilatory threshold 2 $\left(\mathrm{VT}_{2}\right)$ | $102 \mathrm{~L} / \mathrm{min}$ |
|  | 175 latidos $/ \mathrm{min}$ |
|  | $16,1 \mathrm{Km} / \mathrm{h}$ |
| Interval exercise | $\mathbf{8 \times 3} \mathbf{~ m i n ~} \mathbf{8 5} \%$ of $\dot{\mathrm{V}} \mathrm{O}_{\mathbf{2}}$ max |
|  | $\mathbf{1 , 5} \mathbf{~ m i n}$ rest between repetitions |

Table 1

## Objective

To analyze the physiological response to an intermittent exercise at a high intensity.

## Interval exercise data and questions to be asked.

(Figure 1) shows the $\dot{\mathrm{V}} \mathrm{O}_{2}$ and $\dot{\mathrm{V}} \mathrm{CO}_{2}$ for the 8 repetitions performed at $85 \%$ of $\dot{\mathrm{V}} \mathrm{O}_{2}$ max. The average $\dot{\mathrm{V}} \mathrm{O}_{2}$ values corresponding to the changes from the final rest period to the last minute of each of the sets are shown in (Table 1). The average $\dot{\mathrm{VO}}_{2}$ of the changes from rest to each of the 7 sets was $2505 \mathrm{ml} / \mathrm{min}$, i.e. at $90.4 \%$ of the $\dot{\mathrm{V}} \mathrm{O}_{2}$ $\max \left(<\right.$ than $\%$ of $\mathrm{VT}_{2}$ ).

Figure 1: $V O_{-}$2/time function during the 8 repetitions. Note the rapid increase in $\mathrm{V}^{\circ} \mathrm{O}_{-} 2$ during exercise and the decrease in this variable during recovery periods. The straight lines of the $\mathrm{V} \mathrm{O}_{-} \mathrm{O}^{\prime}$ recovery functions are parallel, suggesting no loss of recovery capacity.

| Slopes of the Straight Lines |  |
| :--- | :--- |
| $1^{\mathrm{a}}-2^{\mathrm{a}}$ | 1355,8 |
| $2^{\mathrm{a}}-3^{\mathrm{a}}$ | 1448,4 |
| $3^{\mathrm{a}}-4^{\mathrm{a}}$ | 1459 |
| $4^{\mathrm{a}}-5^{\mathrm{a}}$ | 1414,2 |
| $5^{\mathrm{a}}-6^{\mathrm{a}}$ | 1260,4 |
| $6^{\mathrm{a}}-7^{\mathrm{a}}$ | 1618,4 |
| $7^{\mathrm{a}}-8^{\mathrm{a}}$ | 1556,2 |
| Mean | 1444,62857 |
| Standard Deviation | 110,597103 |

Table 2
For each rest interval, regression lines were calculated. The values of the slopes are shown in (Table 2).

Speed in each of the 8 runs $=14.4 \mathrm{~km} / \mathrm{h}: 85.2 \%$ of the maximum speed in the maximal stress test and $89.4 \%$ of the speed at $\mathrm{VT}_{2}$.

On the basis of the data provided, answer the following question:

1. Is it possible to justify by ergo-spirometric parameters the fact of finishing the intervallic exercise?
2. Compare this woman's response with that of case report 1.

## Answer to the questions raised

Woman in good cardio-respiratory and metabolic conditions, because:

- She has maintained a high speed during intermittent exercise.
$85 \%$ of maximum speed and $89.4 \%$ of speed at $\mathrm{VT}_{2}$.
- In all the repetitions, $\mathrm{RQ}<1$. Although she has produced considerable lactic acid, as it is at all times above ( $10 \%$ of the $\dot{\mathrm{V}} \mathrm{O}_{2}$ corresponding to $\mathrm{VT}_{1}$ and $82 \%$ of the $\dot{\mathrm{V}} \mathrm{O}_{2} \mathrm{max}$ ), she has probably maintained a relatively stable concentration and acid-base state.
- Very relevant, the slopes of the recovery straight lines change very little in the repetitions $(1444 \pm 110 \mathrm{ml} / \mathrm{min})$.

## 2A) Compare this woman's response with that of case report 1

At the same relative intensity in the two women, the woman in case 1 cannot maintain running speed due to the following considerations:

1. The woman in case 1 is not able to maintain a stable $\dot{\mathrm{VO}_{2}}$, while the woman in case 2 maintains this parameter stable.
2. The woman in case 1 reaches a CR $>1$ in the first three series and then equal to 1 , while the woman in case $2^{\prime}$ respiratory quotient has always been below the unit.
3. In each interval, the slopes of the recovery time $/ \stackrel{\mathrm{VO}}{2}$ functions in the case of the woman in case 1 are decreasing, while in the woman in case 2 the slopes are relatively constant.

All of the above indicates that the physical condition of the woman in case 2 is significantly better than that of case 1 . In other words, the cardio-respiratory and metabolic functions show a better response to the intervallic exercise performed.

## Practical Application:

The differences in the slopes of the straight lines could be checked by means of the heart rate:
Case 1: The recovery time/heart rate functions would also be decreasing slopes.
Case 2: The recovery time/heart rate functions would remain stable, as would the slopes of the recovery time $/ \mathrm{V}_{\mathrm{O}}^{2}$ functions.
In summary, high intensity intervallic training can only be applied to people in good physical condition. HIIT needs to be demystified as a method of improving fitness for anyone.
